

ENDOGENOUS DEMAND IN SUPPLY CHAIN NETWORK DESIGN

BEN LILLIJORD AND ALAN LI

MIT SCM CAPSTONE PROJECT

MIT Center for
Transportation & Logistics

AGENDA

Introduction

- Motivation
- Cost minimization vs profit maximization

Methodology

- Model outline
- Endogenous demand incarnations

Analysis

- Sensitivity analysis
- Results

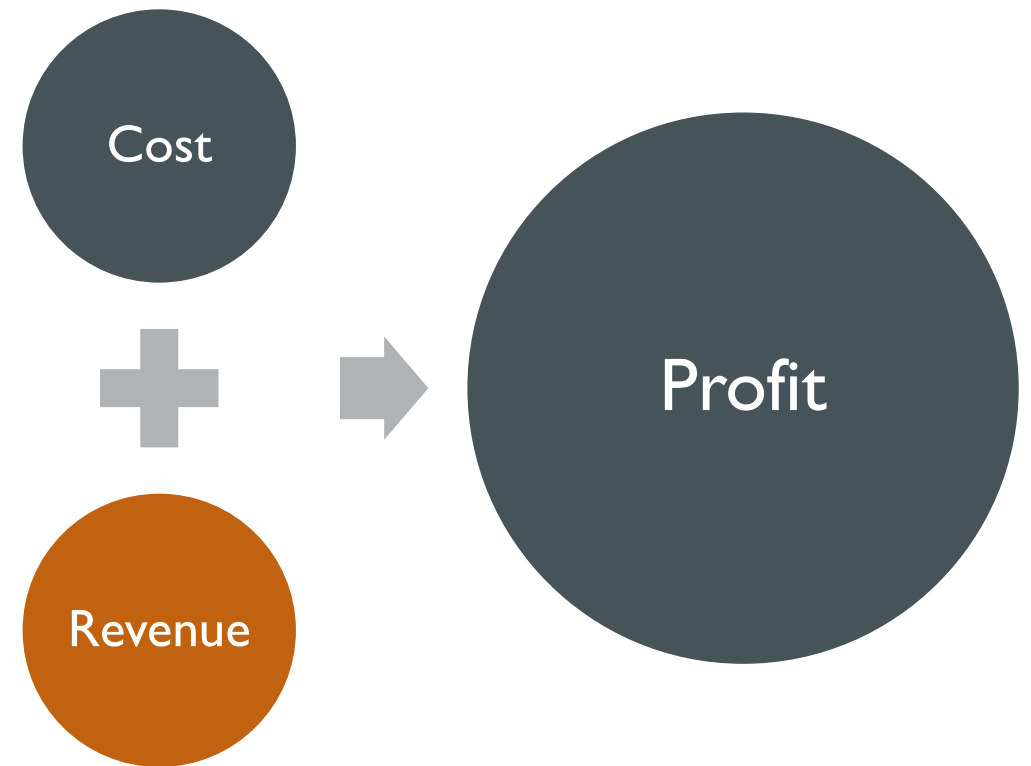

Conclusion

- Summary
- Future Research

INTRODUCTION

MOTIVATION – LOOKING BEYOND COSTS

- What happens when a new facility opens?
 1. Costs incurred
 2. Costs saved
- Any change in revenue?
 1. Better service
 2. Brand recognition

INTRODUCTION

MOTIVATION – PROFIT MAXIMIZATION

Cost Minimization

- Finds low-cost network to meet expected demand
- Considers only costs
- Revenue generation is incidental

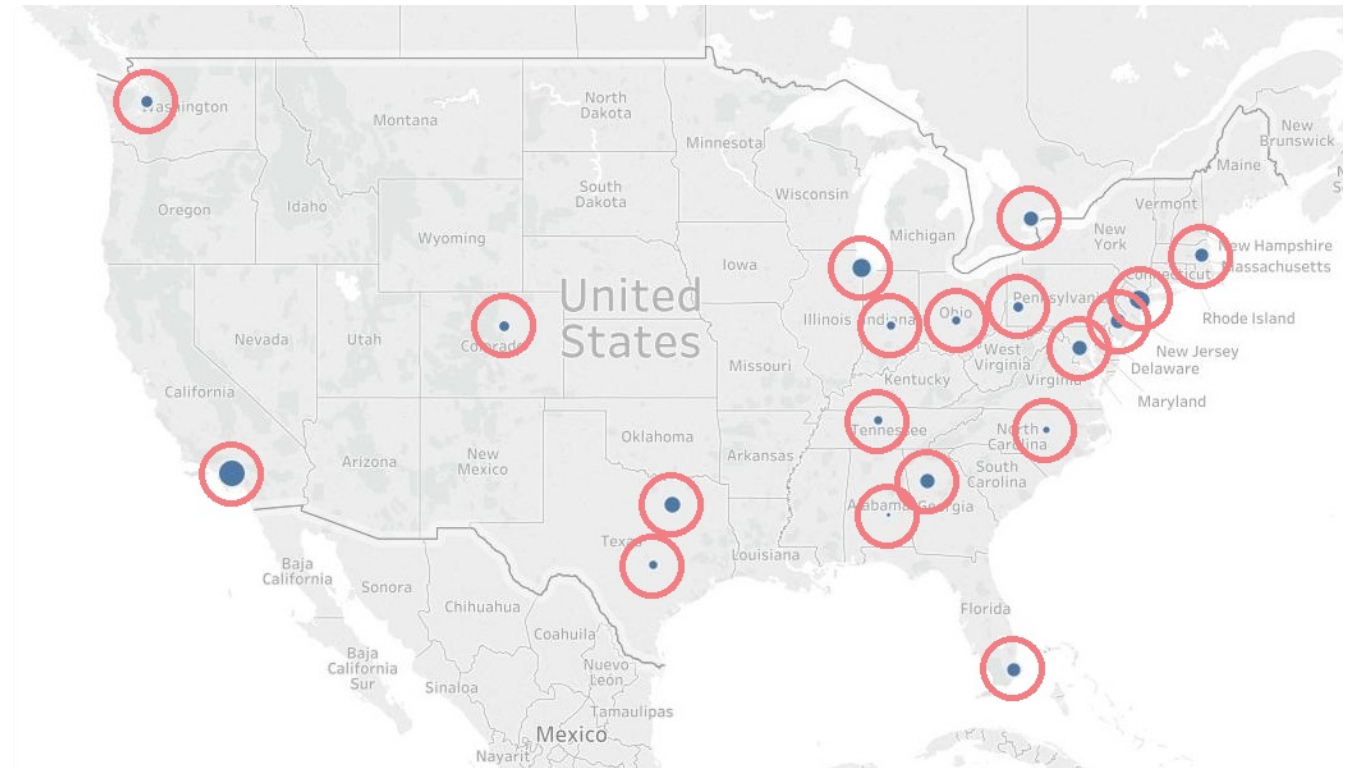

Profit Maximization

- Demand changes depending on network design (Endogenous Demand)
- Considers costs and revenues
- Revenue generation is optimized

ANALYSIS

STEP FUNCTION ENDOGENOUS

- Simplest endogenous model
- Represents same-day shipping
- Demand increases by a set amount for customers near the facility

METHODOLOGY

OBJECTIVE FUNCTIONS & CONSTRAINTS

Objective Functions

Cost minimization objective function:

$$\sum_{i=1} f_i Y_i + \sum_{i=1} \sum_{j=1} c_{ij}(d_{ij}) x_{ij}$$

Profit maximization objective function:

$$\sum_{i=1} \sum_{j=1} [r_{ij} - c_{ij}(d_{ij})] x_{ij} - \sum_{i=1} f_i Y_i$$

Facility Fixed Cost Delivery Cost

Capacity constraint

$$\sum_j x_{ij} \leq k_i, \forall i \in I.$$

Revenue per unit

Linking constraint

$$\sum_j x_{ij} \leq M Y_i, \forall i \in I.$$

Common Constraints

Binary constraint for facilities:

$$Y_i = \{0, 1\}, \forall i \in I.$$

All flow of product must be non-negative:

$$x_{ij} \geq 0, \forall i \in I, \forall j \in J.$$

Demand Constraints

Traditional demand:

$$\sum_i x_{ij} \approx D_j, \forall j \in J.$$

Endogenous demand

$$\sum_i x_{ij} \approx D_j + \sum_i ED_{ij}(d_{ij}), \forall j \in J.$$

METHODOLOGY

ENDOGENOUS DEMAND EFFECT FUNCTION & COEFFICIENT

The general form of the endogenous demand effect function: $\sum_i ED_{ij}(d_{ij}) = \sum_i \frac{\sigma_j Y_i E_{ij}(d_{ij}) x_{ij}}{D_j}, \forall j \in J.$

Quadratic Form

The endogenous demand constraint becomes:

$$\sum_i \left[1 - \frac{\sigma_j Y_i E_{ij}(d_{ij})}{D_j} \right] x_{ij} \approx D_j, \forall j \in J.$$

Endogenous Demand Coefficient

Where:

σ_j is the variation of the demand from customer locations j , for $j \in J$.

$E_{ij}(d_{ij})$ describes the endogenous effect incarnation.

METHODOLOGY

VARIOUS ENDOGENOUS DEMAND COEFFICIENT

METHODOLOGY

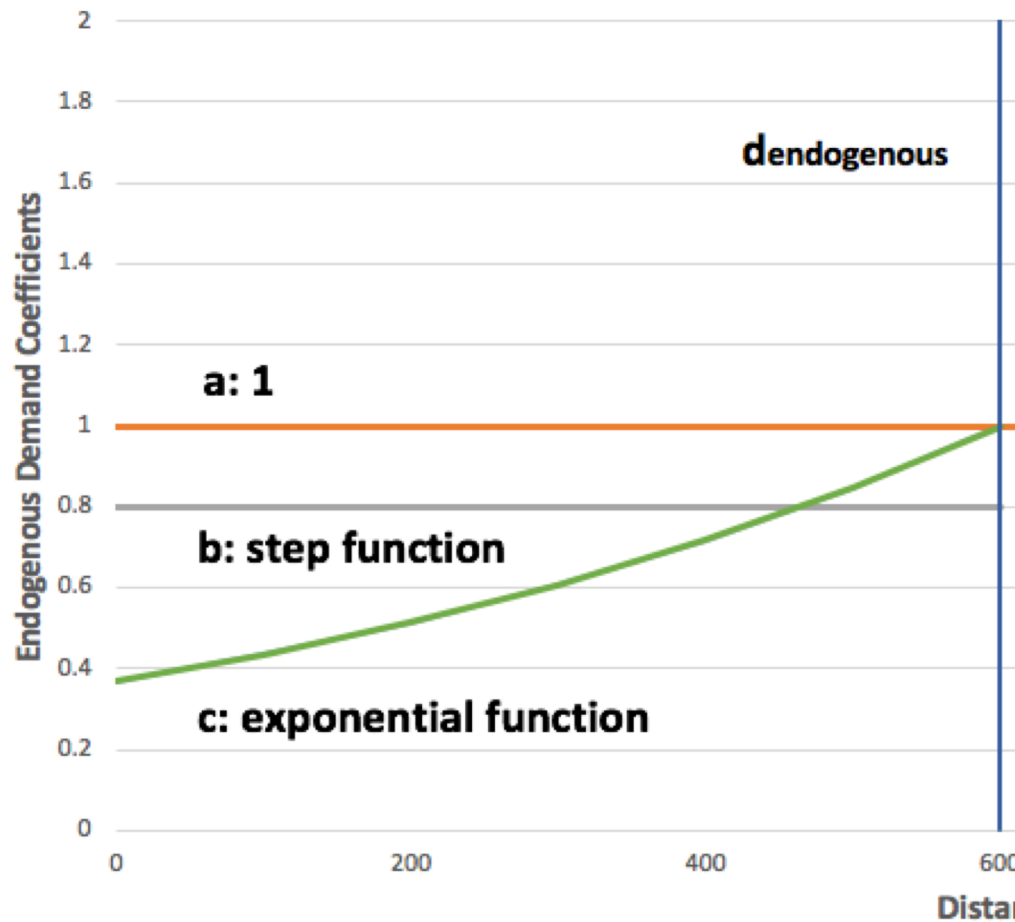

VARIOUS ENDOGENOUS DEMAND COEFFICIENT

METHODOLOGY

VARIOUS ENDOGENOUS DEMAND COEFFICIENT

Endogenous Demand Coefficients under Different Endogenous Effect Incarnation

$$\sum_i \left[1 - \frac{\sigma_j Y_i E_{ij}(d_{ij})}{D_j} \right] x_{ij} \approx D_j, \forall j \in J.$$

$E_{ij}(d_{ij}) = 0$ \rightarrow **Traditional model (a)**

$E_{ij}(d_{ij}) = \text{const.}$ \rightarrow **Step Endogenous model (b)**

$$E_{ij}(d_{ij})_{Exp} = -5 * \left(e^{\left(\frac{d_{ij} - d_{endogenous}}{d_{endogenous}} \right)} - 1 \right),$$

\rightarrow **Exponential Endogenous model (c)**

❖ Product/industry specific function form available from regression of market research data

ANALYSIS

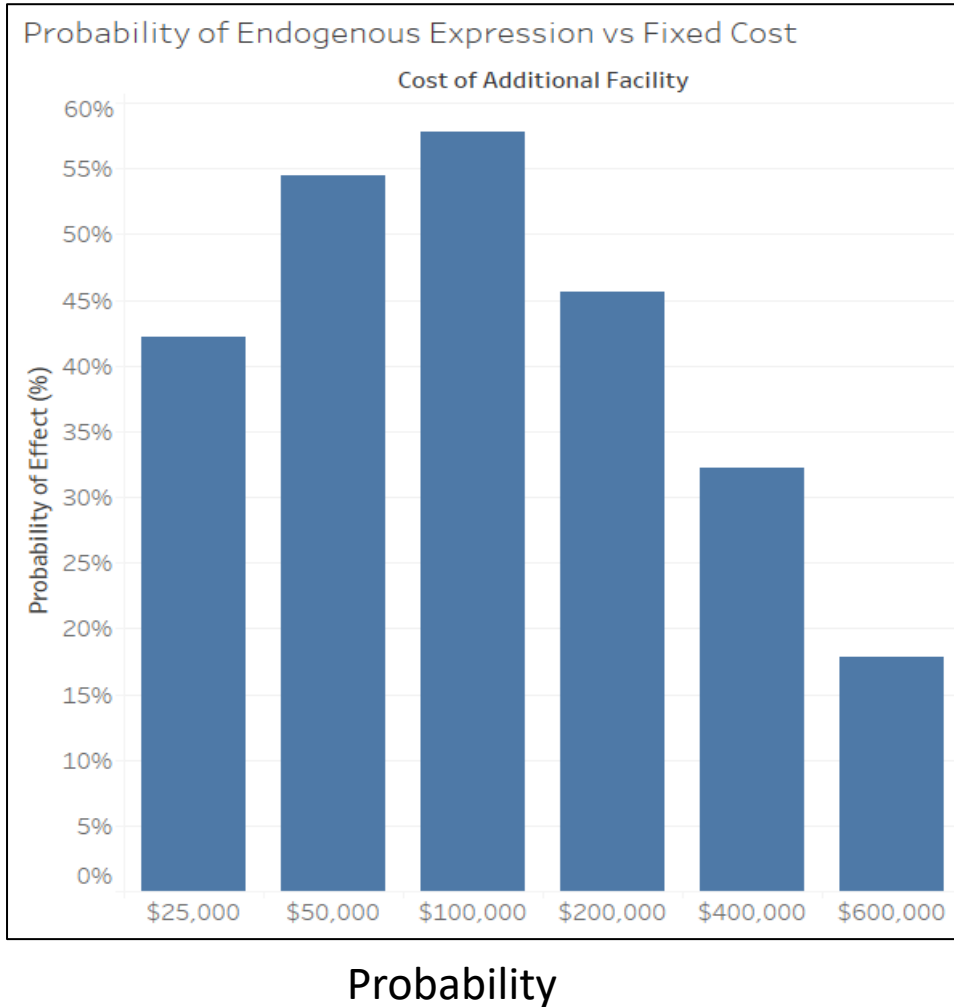

SENSITIVITY ANALYSIS

- The analysis is performed in **Python** with **IBM CPLEX** Optimizer. Each combination of metrics was tested in a total of 40,320 runs and 1,260 optimal solutions in the sensitivity analysis alone.
- Assumptions
 - Unconstrained capacity
 - Step Endogenous Incarnation
 - Focus on network design corresponding fixed cost and delivery (linehaul) cost
 - Direct distance by using Haversine formula with longitude and latitude of each city
 - Demand in each region is simplified to be concentrated and located in the city centroid
- Combination of matrices
 - Fixed cost of an additional facility (values from \$25,000 to \$600,000).
 - Variable per mile cost of shipping goods (values from \$0.005 to \$0.15).
 - Total demand at each demand center (values from 2,000 to 20,000).
 - Variable demand from endogenous effects (values from 300 to 1,500).

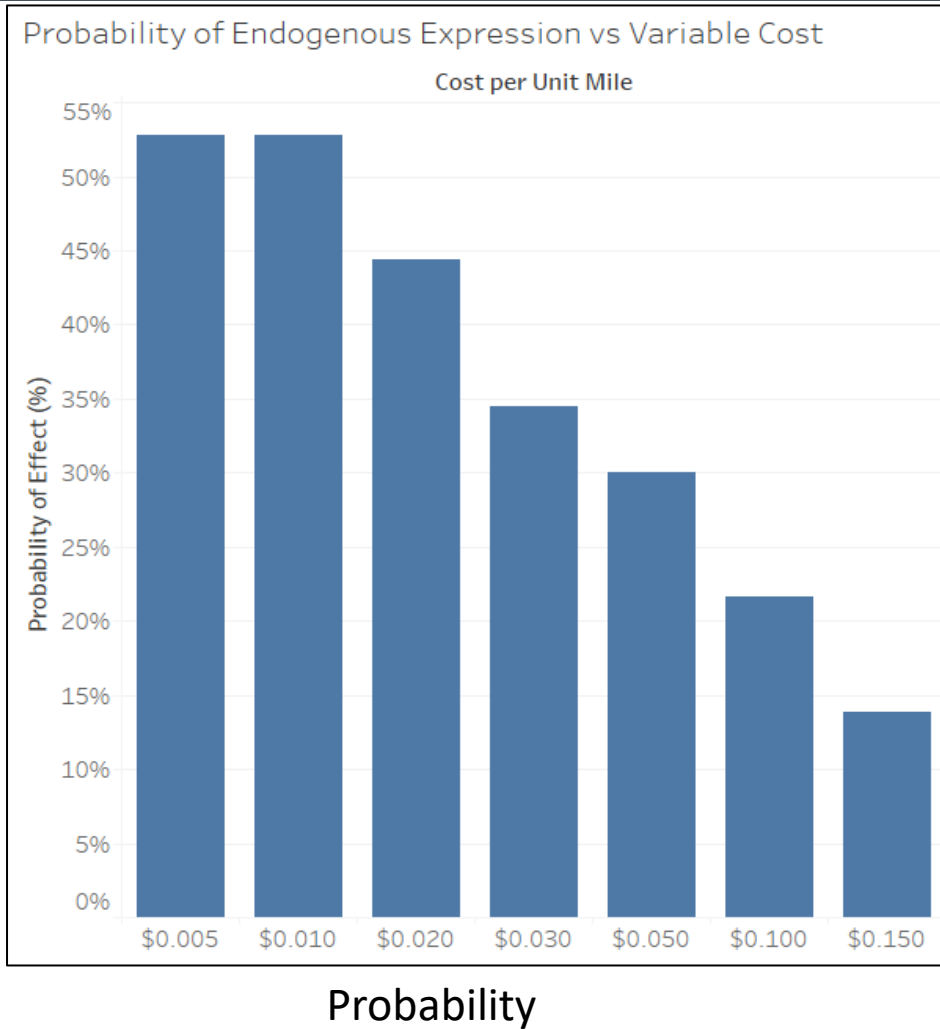

ANALYSIS

ENDOGENOUS EXPRESSION VS FIXED COST OF FACILITY

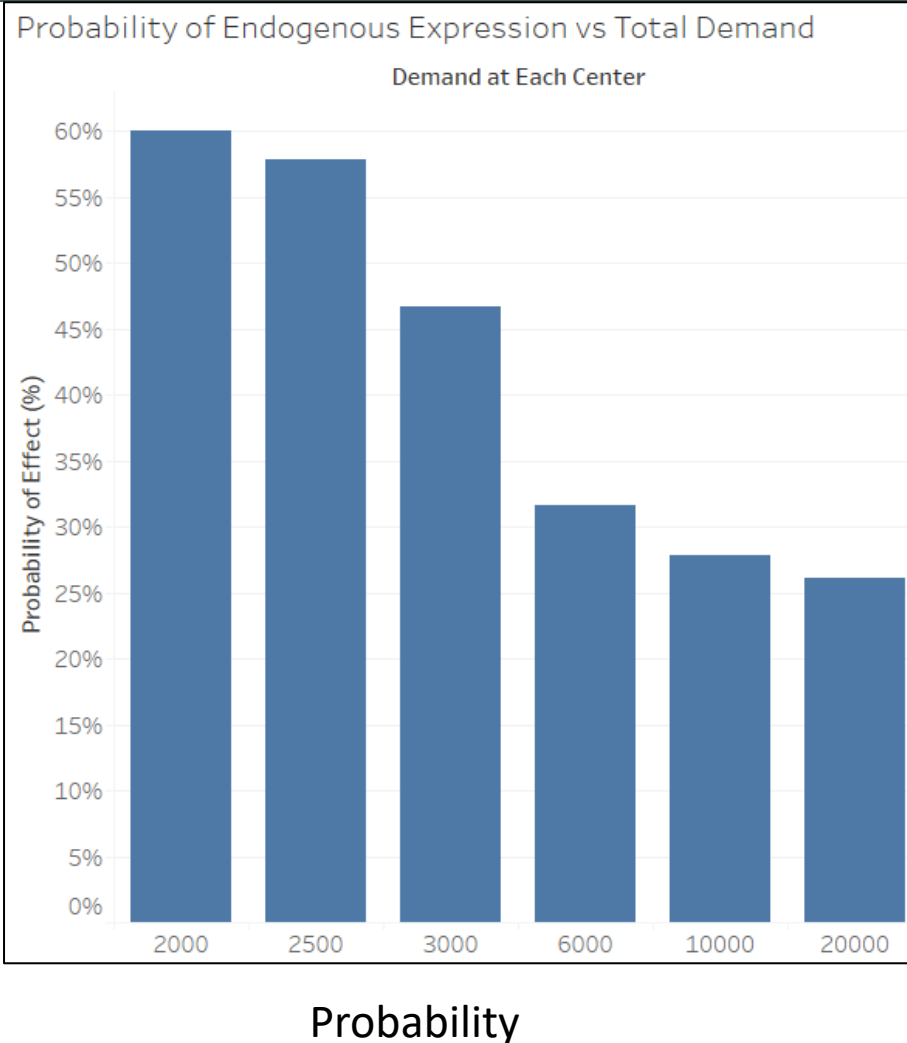

ANALYSIS

ENDOGENOUS EXPRESSION VS COST PER UNIT MILE

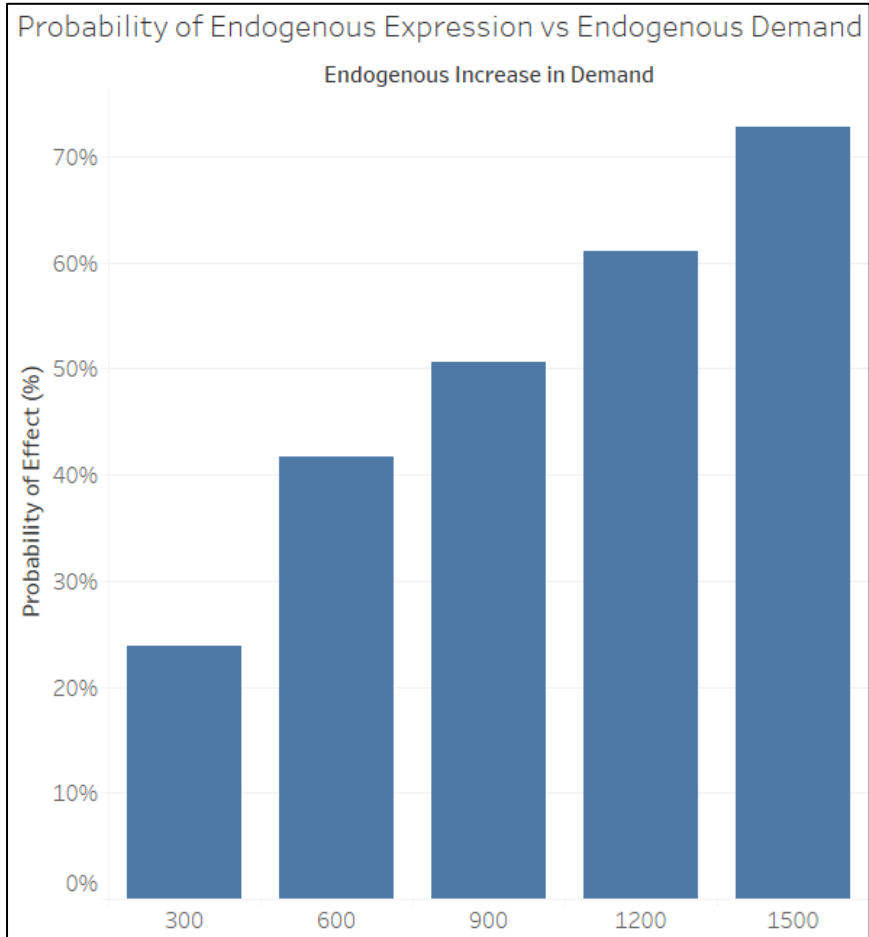

ANALYSIS

ENDOGENOUS EXPRESSION VS TOTAL DEMAND

ANALYSIS

ENDOGENOUS EXPRESSION VS VARIABLE DEMAND

Probability

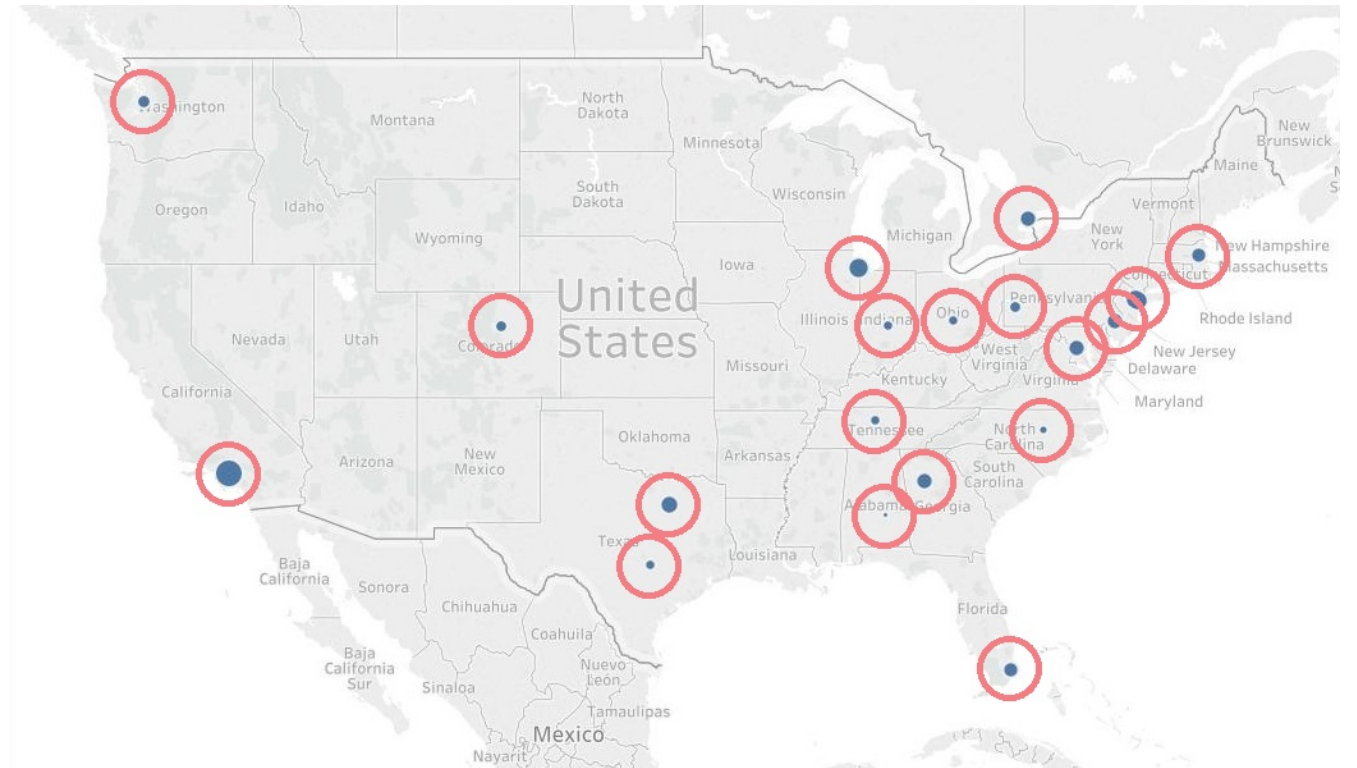

Profit Margin Improvement

ANALYSIS

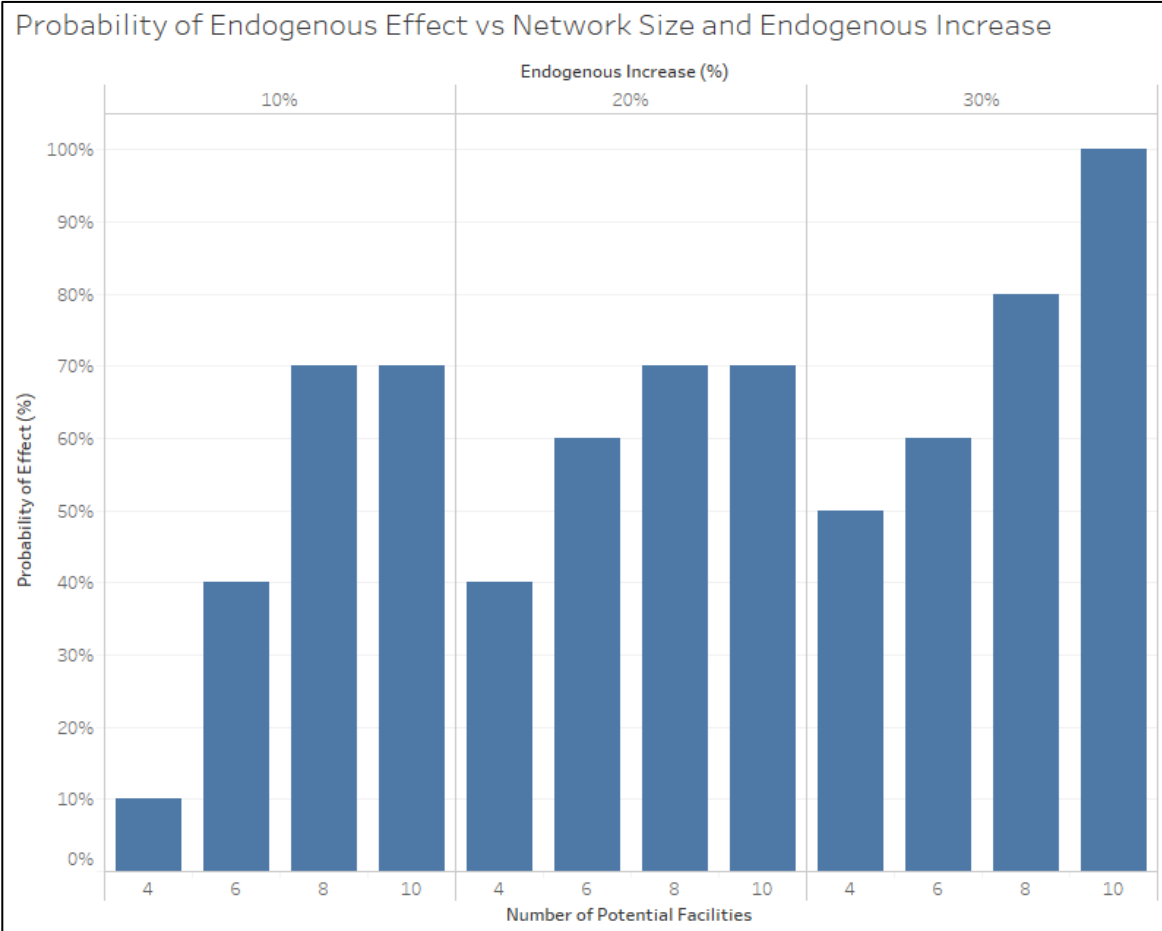

STEP FUNCTION ENDOGENOUS

- Profit increases as high as 10.2%
- Under favourable conditions, average profit increase of 3.2%
- More profitable network found in nearly half of the simulations at only 10% endogenous effect
- Complex networks tend to see greater benefits

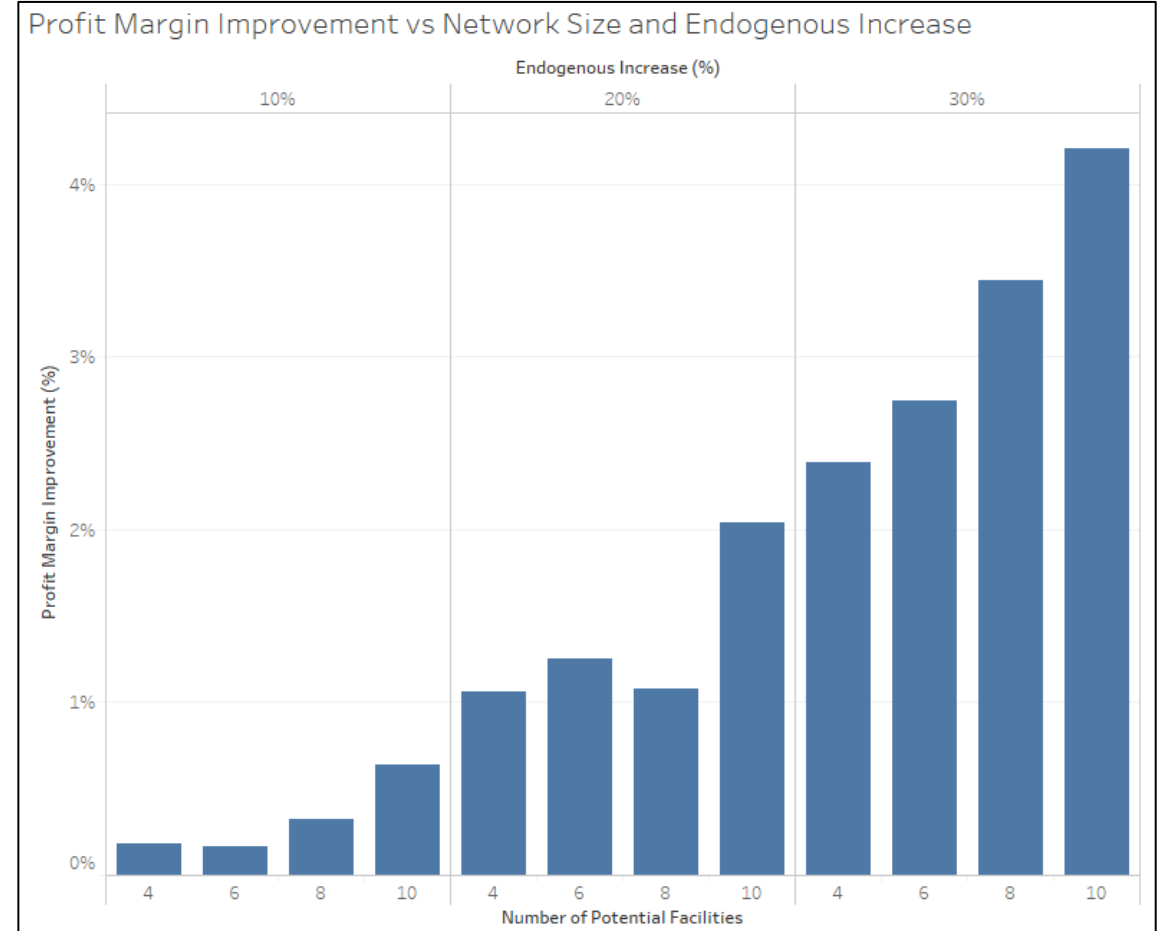

ANALYSIS

ENDOGENOUS EXPRESSION – STEP FUNCTION

Probability

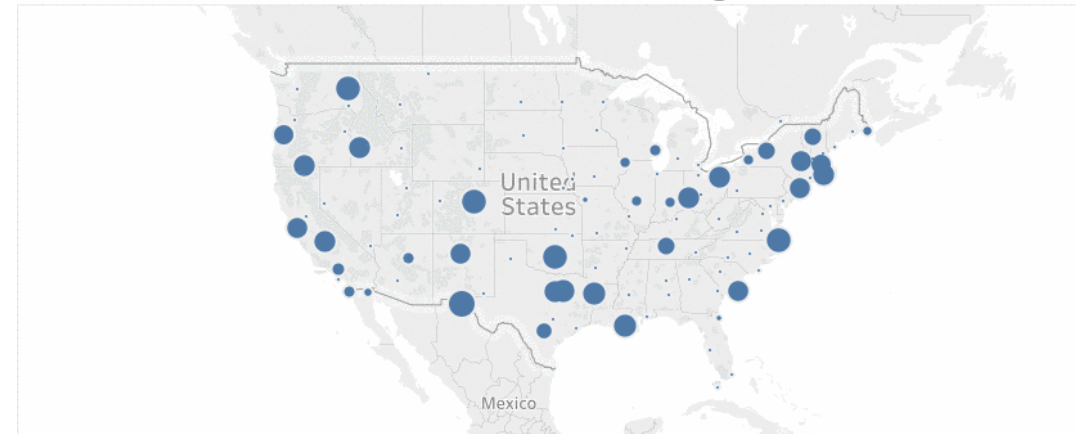

Profit Margin Improvement

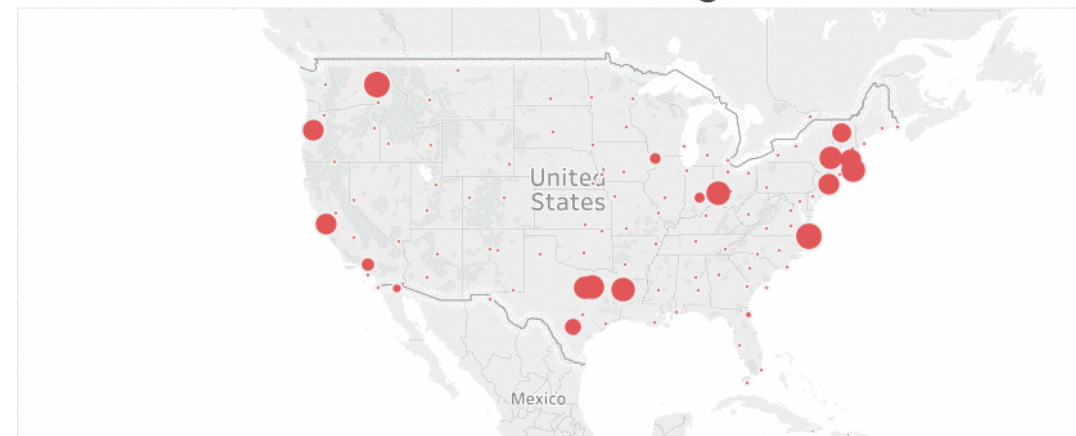

ANALYSIS NETWORK EXPANSION PROBLEM

- Common problem: decision to add one or more facilities
- Average Return On Assets increased by 10% with profit maximizing model
- Promotes faster network expansion
- The profit maximization model often chose locations that were never chosen by the cost minimization model

Profit Maximizing

Cost Minimizing

CONCLUSION

SUMMARY OF RESULTS

- Three significant findings:
 1. Even small endogenous effects result in network changes
 2. The profit maximization model was more valuable in complex networks
 3. Profit maximization model tends to place facilities closer to demand centers

CONCLUSION

FUTURE RESEARCH

■ Applications

- Perform demand analysis for specific industry to estimate potential for endogenous effect and model incarnation

■ Capacitated facility study

- Use the uncapacitated model in this thesis as a basis, future research can work on capacitated problem

■ Distance for route between each pair of facility and client

- Change the direct distance by using Haversine formula with longitude and latitude to real route with google map API
